why this collaboration?

- 1T-magnet and 4 GeV/c hadron beam available at KEK
 - 2 TPCs existing at Carleton (Ottawa) and MPI (Munich)
 - read-out technologies developed previously at Saclay (Micromegas) and Carleton (resistive layer)
+ many people enthusiast to cooperate !
- 3 weeks of beam data taking in 2005 (June and October)

outline

- why a resistive layer ?
 - how does it work ?
 - experimental set-up (TPCs and beam)
 - PRF and spatial resolution results
 - future and conclusion
- } remind!

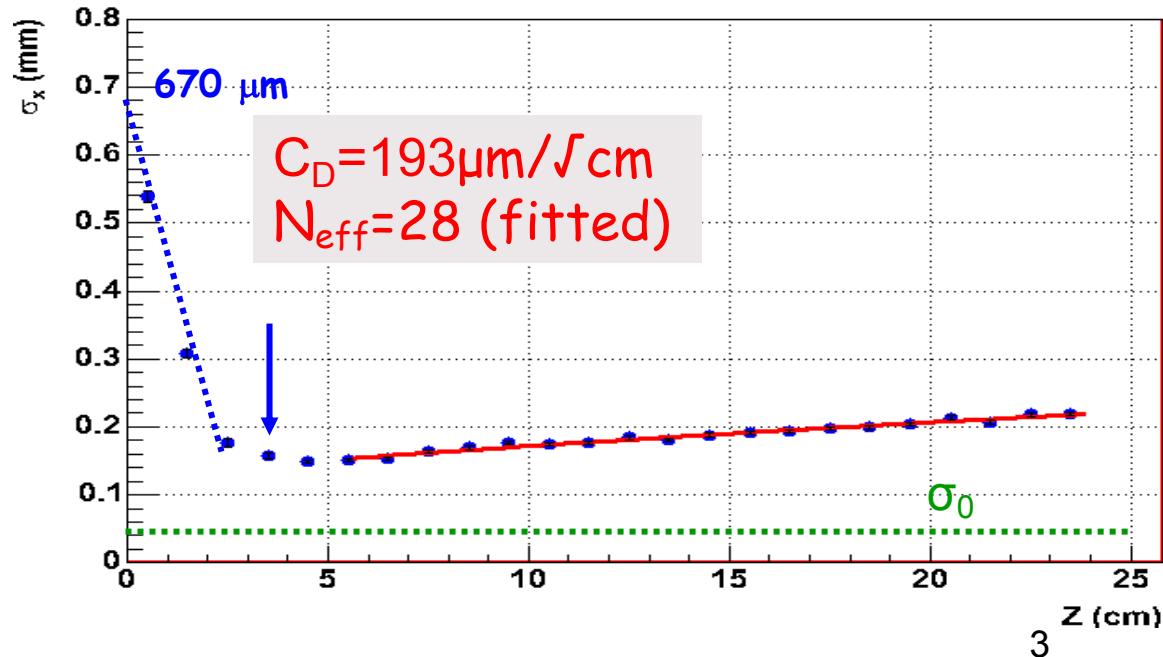

why a resistive layer ?

transverse resolution from the full simulation of the of the MPI Micromegas TPC (by Khalil Boudjemline, Carleton, Ottawa), with these characteristics:

$2.3 \times 6.3 \text{ mm}^2$ pads, Ar- $i\text{C}_4\text{H}_{10}$: 95-5%, $B = 1\text{T}$, $E=200\text{V/cm}$, mean gain= 10000

the spatial transverse resolution results from three contributions:

- a constant term σ_0 mainly due to electronics, noise, ...
- a term coming from the finite pad width s ($s/\sqrt{12} \approx 670\mu\text{m}$ for $\Phi \approx 0$, $Z=0$)
- a diffusion term $\propto \sqrt{Z}$ (and $\propto 1/\sqrt{N_{\text{eff}}}$)

how to extrapolate the transverse resolution to:

a 250cm long TPC with a low diffusion gas mixture

for example Ar-CF₄ at 4T, C_d=25 μm/√cm (200) with ω_T≈20 (2.5)

how to decrease (suppress) the pad width contribution?

1. **decrease** by a factor (>5?) the **pad width** $\Rightarrow 10^7$ channels
irrealistic (loss of resolution with Φ angle)

but leads to a new promising concept of digital TPC:

minipads ($\ll 1\text{mm}^2$), with **single electron** detection

(see presentations by Jan Timmermans , Klaus Desch & Michael Hauschild)

2. **diffuse electrons AFTER** multiplication (proposed by VL)

«impossible» with Micromegas

difficult with GEM: needs for $\sigma_{\text{diff}} \approx 700\text{-}800\mu\text{m}$ (for 2mm pad width),

i.e. typically $\sim 3\text{cm}$ defocusing at 2-3 kV/cm

3. **set a resistive foil** on the pad plane

proposed by Madhu Dixit (Carleton, Ottawa) ~ 4 years ago

idea:

a uniform high resistivity $1 \text{ M}\Omega/\square$ Al-Si Cermet is glued on the pad plane

for more info: see presentation by Madhu Dixit at the ILC 2005 Snowmass workshop

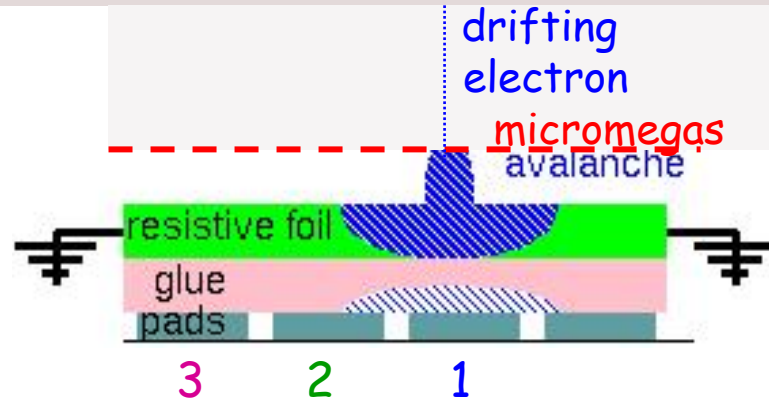

charge dispersion with a resistive anode

- Micromegas anode with a highly 50μm resistive film bonded to a readout plane with an insulating spacer.
- 2-dimensional continuous RC network defined by material properties(R) & geometry (C).
- point charge at $r = 0$ & $t = 0$ disperses with time.
- time dependent anode charge density sampled by readout pads.

the charge evolution in r and t is the "telegraph" equation, governed by the RC time constant parameter:

$$\frac{\partial \rho}{\partial t} = \frac{1}{RC} \left[\frac{\partial^2 \rho}{\partial r^2} + \frac{1}{r} \frac{\partial \rho}{\partial r} \right]$$

$$\Rightarrow \rho(r, t) = \frac{RC}{2t} e^{-\frac{r^2 RC}{4t}}$$

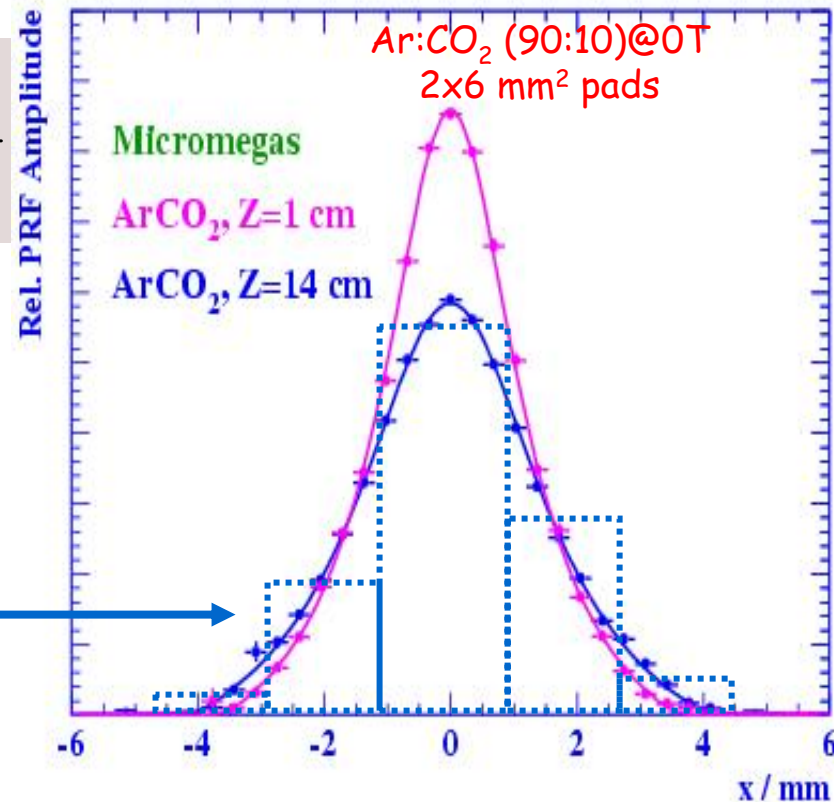

TPC track PRFs with Micromegas

- the PRF (Pad Response Function) is **not Gaussian**
- the PRF depends on track position relative to the pad PRF = PRF(x,z)
- PRF can be characterized by its **FWHM $\Gamma(z)$** & **base width $\Delta(z)$** .
- PRFs determined from the data have been fitted to a functional form consisting of a ratio of two symmetric 4th order polynomials.

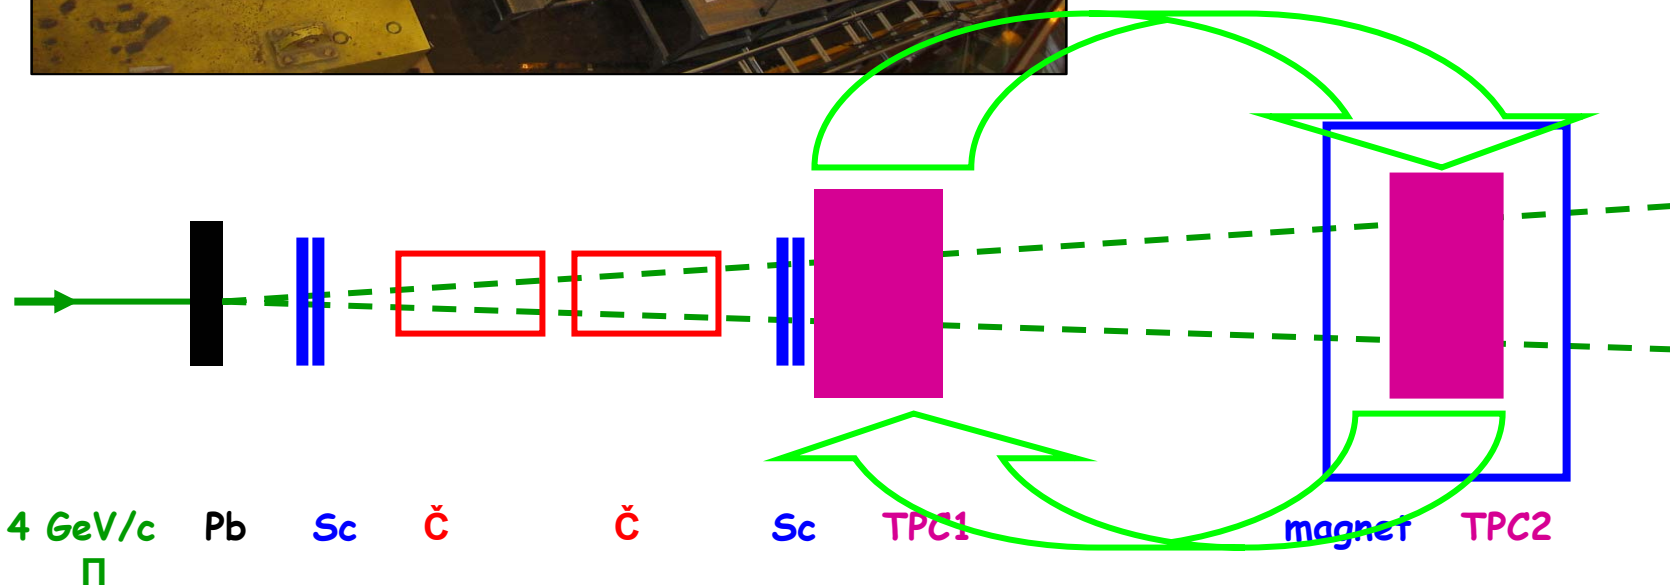

$$PRF[x, \Gamma(z), \Delta, a, b] = \frac{(1 + a_2 x^2 + a_4 x^4)}{(1 + b_2 x^2 + b_4 x^4)}$$

a_2, a_4, b_2 & b_4 can be written down in terms of Γ and Δ & two scale parameters a & b .

the PRF fits well with at least three pads

experimental set-up at KEK: the beam line

experimental set-up at KEK: the two TPC's

Carleton Ottawa TPC

- Micromegas mesh 10x10 cm²
- drift distance: 16 cm
- 126 2.3 x 6.3 mm² pads in 7 rows
- ALEPH preamps + 25MHz Montréal FADC
- gas mixtures:
 - Ar-5%isoC₄H₁₀ B=1T, 80keVts@220&80V/cm
 - Ar-10%CO₂ B =0T, 80keVts
- evt rate ~3Hz (2.5 Gb/hr).
- beam $\pi^+/\pi^-/e$

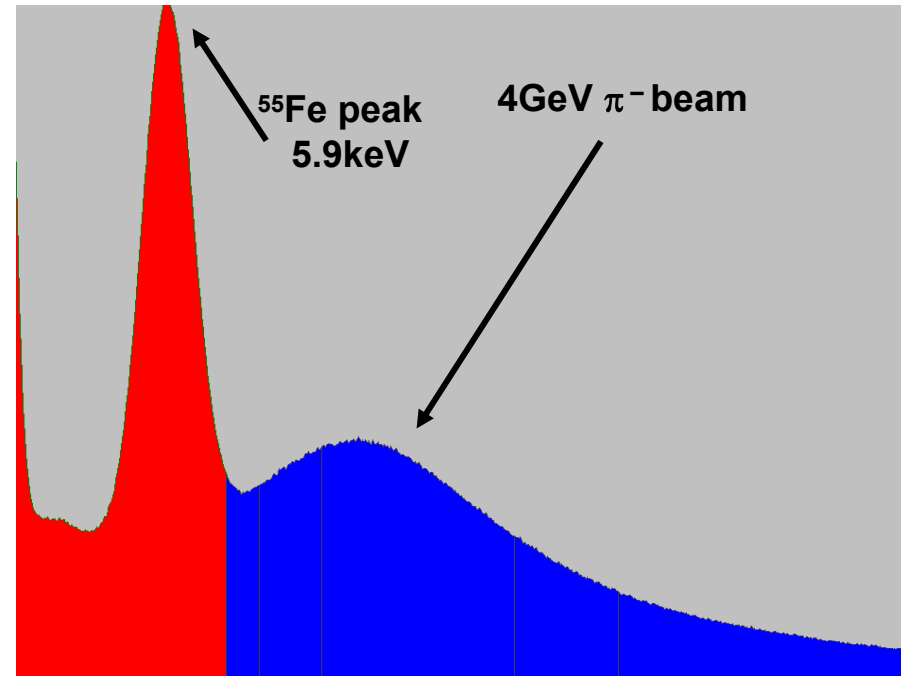

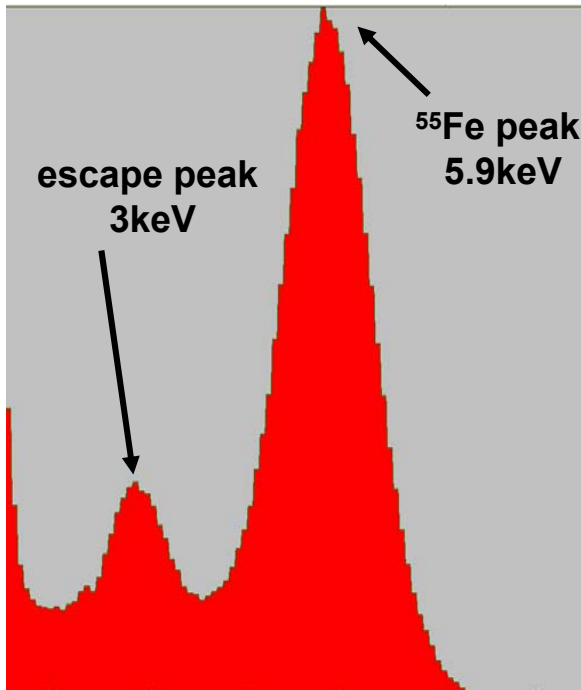

MPI+Saclay-Orsay TPC

- Micromegas mesh 10x10 cm²
- drift distance 26cm
- 512 2x6.3 mm² pads in 16 rows
- ALEPH preamps + 11MHz FADC
- gas mixtures:
 - Ar-5%isoC₄H₁₀ B=1T, 19keVts@220V/cm
 - " B=1T, 20keVts@80V/cm
 - " B=1T, 11keVts@ $\Phi=10^\circ$
 - Ar-10%CO₂ B=0T, 14 keVts
- evt rate ~0.3Hz
- beam $\pi^+/\pi^-/e$

low momentum particle ($r=3.5\text{cm}$ at 1T)

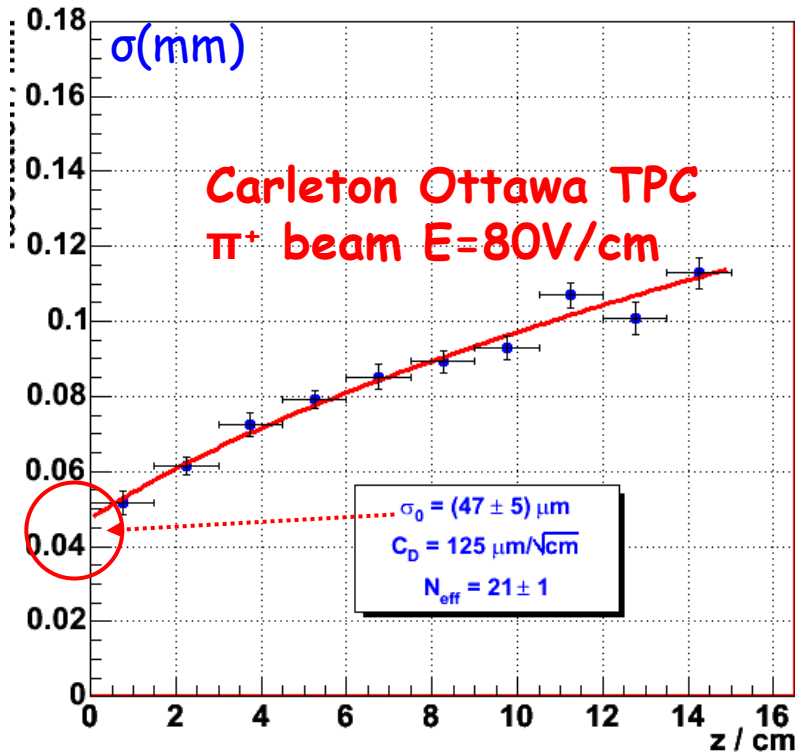

results: PRF vs Z

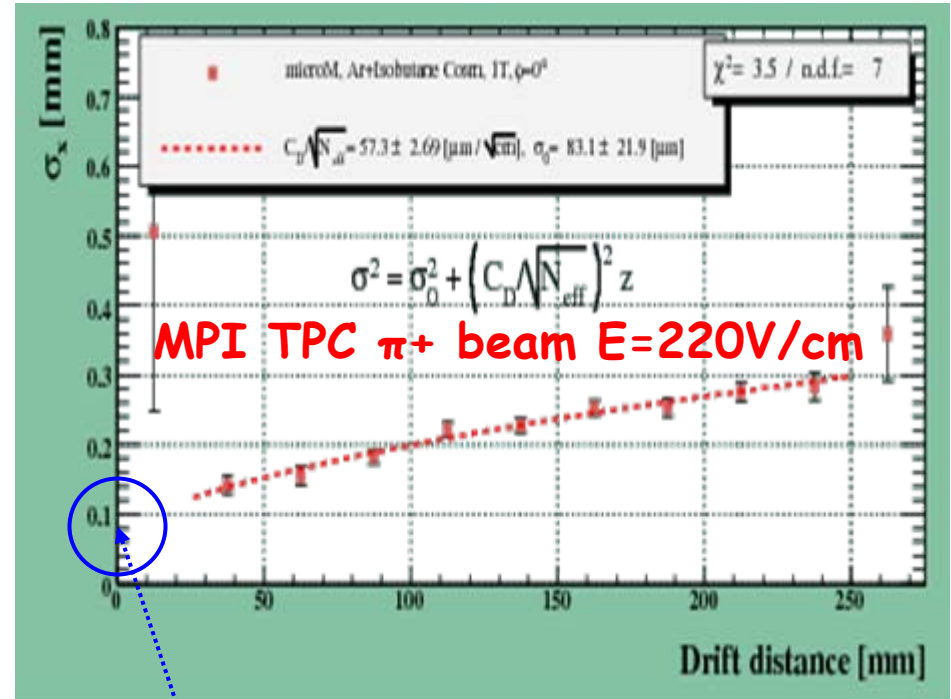

Ar/iC₄H₁₀:95/05@1T

results: resolution vs Z

Ar/iC₄H₁₀:95/05@1T

preliminary

$\sigma_0 = 83 \pm 22 \mu\text{m}$

$C_D/\sqrt{N_{\text{eff}}} = 57 \pm 3 \mu\text{m}/\sqrt{\text{cm}}$

VERY preliminary!!
analysis program not
optimised for PRF

conclusion and future

- it has been proven that a transverse resolution of $\sim 50\mu\text{m}$ has been achieved.
 - a resistive foil allows to suppress the limitation on the resolution due to the pad width
 - with a resistive foil, and a low diffusion gas ($C_d \sim 25\mu\text{m}/\sqrt{\text{cm}}@4\text{T}$), the PRF will be \sim independant of the drift distance
(for example, for the choice made for this experiment, the PRF should increase from 2mm at $Z=0$ to 2.2mm at $Z=2.5\text{m}$)
the compromise should be (easily) done between the gas mixture, the pad width and the foil resistivity \rightarrow more flexibility for the construction
 - more work to be done on the data analysis and also many data to be analysed.
 - new tests in the future?
 - no more beam at KEK
 - DESY or CERN? with JACEE?
 - new cosmic data?
with the Saclay-Orsay-Berkeley TPC?
- many thanks to the KEK support
(management and technical teams)
